as in the triglyceride-rich lipoproteins. In treating a patient with dyslipidemia, one should attempt to achieve the target LDL-C goal as well as a normal triglyceride value below 150 mg/dL (1.70 mmol/L). In this manner the target non–HDL-C goal will be achieved and the LDL particle size improved.

Correction

Errors in “Abstract” Section. In the Original Investigation by Muñoz et al titled “Bloodstream Infections After Invasive Nonsurgical Cardiologic Procedures,” published in the September 24, 2001, issue of the ARCHIVES (2001;161:2110-2115), 2 errors occurred in the “Abstract” section on page 2110. In the second sentence of the “Results,” the percentage for the overall incidence of bacteremia should have read “0.06% after diagnostic cardiac catheterization” and “0.08% after electrophysiologic studies.”
